

Capacitor protection device alarm reason

Overview

This overcurrent relay detects an asymmetry in the capacitor bank caused by blown internal fuses, short-circuits across bushings, or between capacitor units and the racks in which they are mounted. Each capacitor unit consists of a number of elements protected by internal fuses. Faulty elements in a capacitor unit are. Capacitors of today have very small losses and are therefore not subject to overload due to heating caused by overcurrent in the circuit. The capacitor can withstand 110% of rated voltage continuously. The capability curve then. In addition to the relay functions described above the capacitor banks need to be protected against short circuits and earth faults. This is done with an ordinary two- or three-phase short circuit protection combined with an earth.
